

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

# KEY TO THE PRONUNCIATION AND TO THE ABBREVIATIONS AND SIGNS EMPLOYED.

## PRONUNCIATION.

IN showing the pronunciation the simplest and most easily understood method has been adopted, that of *re-writing* the word in a different form. In doing so the same letter or combination of letters is made use of for the same *sound*, no matter by what letter or letters the sound may be expressed in the principal word. The *key* by this means is greatly simplified, the reader having only to bear in mind one mark for each sound.

### Vowels.

h, . . . . . " . . . . . Fr. <i>ton</i> .	zh, . . . . . " . . . . . azure.
ng, . . . . . " . . . . . sing.	

The application of this key to the pronunciation of foreign words can as a rule only represent approximately the true pronunciation of those words. It is applicable, however, to Latin and Greek words, as those languages are pronounced in England.

**Accent.**—Words consisting of more than one syllable receive an accent, as the first syllable of the word *labour*, the second of *delay*, and the third of *comprehension*. The accented syllable is the most prominent part of the word, being made so by means of the accent. In this dictionary it is denoted by the mark '. This mark, called an accent, is placed above and beyond the syllable which receives the accent, as in the words *la'bour*, *de'lay*, and *comprehen'sion*.

Many polysyllabic words are pronounced with two accents, the primary and the secondary accent, as the word *excommunication*, in which the third, as well as the fifth syllable is commonly accented. The accent on the fifth syllable is the primary, true, or tonic accent, while that on the third is a mere euphonic accent, and consists of a slight resting on the syllable to prevent indistinctness in the utterance of so many unaccented syllables. Where both accents are marked in a word, the primary accent is thus marked ', and the secondary, or inferior one, by this mark ' , as in the word *excommu'nica'tion*.

## CHEMICAL ELEMENTS AND SYMBOLS.

By means of chemical symbols, or formulas, the composition of the most complicated substances can be very easily expressed, and that, too, in a very small compass. An abbreviated expression of this kind often gives, in a single line, more information as to details than could be given in many lines of letterpress.

When any of the above symbols stands by itself it indicates one atom of the element it represents. Thus, H stands for one atom of hydrogen, O for one atom of oxygen, and Cl for one atom of chlorine. (See *ATOM*, and *Atomic theory* under *ATOMIC*, in Dictionary.)

When a symbol has a small figure or number under-written, and to the right of it, such figure or number indicates the number of atoms of the element. Thus—O<sub>2</sub>, signifies two atoms of oxygen, S<sub>5</sub> five atoms of sulphur, and C<sub>10</sub> ten atoms of carbon.

When two or more elements are united to form a chemical compound, their symbols are written one after the other, to indicate the compound. Thus—H<sub>2</sub>O means water, a compound of two atoms of hydrogen and one of oxygen; C<sub>12</sub>H<sub>22</sub>O<sub>11</sub> indicates cane-sugar, a compound of twelve atoms of carbon, twenty-two of hydrogen, and eleven of oxygen.

These two expressions as they stand denote respectively a molecule of the substance they represent, that is, the smallest possible quantity of it capable of existing in the free state. To express several molecules a large figure is prefixed, thus: 2 H<sub>2</sub>O represents two molecules of water, 4 (C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>) four molecules of cane-sugar.

When a compound is formed of two or more compounds the symbolical expressions for the compound are usually connected together by a comma; thus, the crystallized magnesian sulphate is MgSO<sub>4</sub>, 7 H<sub>2</sub>O. The symbols may also be used to express the changes which occur during chemical action, and they are then written in the form of an equation, of which one side represents the substances as they exist before the change, the other the result of the reaction. Thus, 2 H<sub>2</sub> + O<sub>2</sub> = 2 H<sub>2</sub>O expresses the fact that two molecules of hydrogen, each containing two atoms, and one of oxygen, also containing two atoms, combine to give two molecules of water, each of them containing two atoms of hydrogen and one of oxygen.

# THE IMPERIAL DICTIONARY

## OF THE ENGLISH LANGUAGE.

### SCREAM

**Scream** (skrem), v.t. [Comp. Icel. skreima, to scream, probably imitative, like screech, shriek, &c.] 1. To cry out with a shrill voice; to utter a sudden, sharp outcry, as in a fright or in extreme pain; to utter a shrill, harsh cry; to shriek.

I heard the owl scream and the crickets cry.

So sweetly screams if it (a mouse) comes near her. She ravishes all hearts to hear her.

2. To give out a shrill sound; as, the railway whistle screamed.

**Screech** (skresh), n. 1. A shriek, or sharp shrill cry uttered suddenly, as in terror or in pain. 'Screeches of horror rend the affrighted skies.' Pope. — 2. A sharp, harsh sound. 'The screech of a madden'd beach dragg'd down by the wave.' Tennyson.

**Screecher** (skresh'er), n. 1. One that screams. 2. A name given to two species of South American gnatcatcher birds, the *Palamedea cornuta* and *Chamaea chamea*. They are remarkable for their harsh and discordant voices, and for the sharp hard spurs with which the wings are armed. See PALAMEDEA. 3. Something very great, a whacker; a bounding fellow or girl. (Slang.)

**Screaming** (skresh'ing), p. and a. 1. Crying or sounding shrilly. — 2. Causing a scream, as, a screaming farce, one calculated to make the audience scream with laughter.

**Scree** (skre), n. [Comp. Icel. skreia, a lance slip on a hill-side.] A small stone or pebble; in the pl. debris of rocks, shingle, a talus; accumulations of loose stones and fragments at the base of a cliff or precipice. 'Grey cairns and scree of granite.' Kingsley.

Before I had got half way up the scree, which gave way and rattled beneath me at every step.

**Screech** (skresh), v.i. [A softened form of scream (which see), Icel. skreika, skreita, to screech, skreikr, a screech, Sw. skrika, Dan. skrike, to screech; an imitative word, comp. Sc. screich, Gael. screach, W. ysprechian, to screech.] To cry out with a sharp, shrill voice, to scream; to shriek. 'The screech-owl screeching loud.' Shak.

These birds of night . . . screeched and clapped their wings for a while.

**Screech** (skresh), n. 1. A sharp, shrill cry, such as is uttered in acute pain or in a sudden fright; a harsh scream. 'The birds obscene . . . with hollow screeches.' Pope.

A screech or shriek is the cry of terror or passion, perhaps it may be called sharper and harsher than a scream, but in human beings especially, scarcely to be distinguished from it.

2. A sharp, shrill noise; as, the screech of a railway whistle.

**Screech-owl** (skresh'owl), n. An owl that utters a harsh, disagreeable cry at night, formerly supposed to be ominous of evil; an owl, as the barn-owl, that screeches, in opposition to one that hoots.

The owl at Freedom's window scream'd, The screech-owl, prophet dire.

**Screechy** (skresh'i), a. Shrill and harsh, like a screech. Cockburn.

**Screed** (skred), n. [Prov. E. screed, a shred, A Sax. screde, a shred See next entry.] In plastering, (a) a strip of mortar of about 6 or 8 inches wide, by which any surface about to

be plastered is divided into bays or compartments. The screeds are 4, 5, or 6 feet apart, according to circumstances, and are accurately formed in the same plane by the plumb-rule and straight-edge. They thus form gauges for the rest of the work, the interspaces being latterly filled out flush with them. (b) A strip of wood similarly used.

**Screed** (skred), n. [A form of shred; a Scotch word. See above.] 1. The act of rending or tearing; a rent; a tear. Burns. — 2. That which is rent or torn off; as, a screed of cloth. 3. A piece of poetry or prose, a harangue; a long tirade upon any subject. — A screed o' drink, a drinking bout. Sir W. Scott.

**Screed** (skred), v.t. [Sc. See the noun.] 1. To rend, to tear. — 2. To repeat glibly; to dash off with spirit. Burns.

**Screcket** (skresh), v.i. Same as Screech.

**Screen** (skren), n. [O Fr. ecran, ecrain, ecran, Fr. écran, a screen, perhaps from O H G skrunna, a bench, a table.] 1. An appliance or article that shelters from the sun, rain, cold, &c., or from sight; a kind of movable framework or partition, often hinged so that it may be opened out more or less as required, or be folded up to occupy less space, used in a room for excluding cold, or intercepting the heat of a fire. 'Your lenly screens.' Shak.

Our fathers knew the value of a screen From seditious suns.

2. That which shelters or protects from danger; that which hides or conceals, or which prevents inconvenience.

Some ambitious men seem as screens to princes in matters of danger and envy.

3. A kind of riddle or sieve; more especially, (a) a sieve used by farmers for sifting earth or seeds. (b) A kind of wire sieve for sifting

as to shut out an aisle from the choir, a private chapel from a transept, the nave from the choir, the high altar from the east end of the building, or an altar tomb from a public passage of the church. See PAR-CLOSE. (c) In medieval halls, a partition extending across the lower end, forming a lobby within the main entrance doors, and having often a gallery above. (d) An architecturally decorated wall, inclosing a courtyard in front of a building. — 5. Next, the name given to a piece of canvas hung round a berth for warmth and privacy.

**Screen** (skren), v.t. [From the noun.] 1. To shelter or protect from inconvenience, injury, or danger; to cover; to conceal; as, our houses and garments screen us from cold; an umbrella screens us from rain and the sun's rays, to screen a man from punishment.

Back'd with a ridge of hills, That screen'd the fruits of th' earth.

2. To sift or riddle by passing through a screen, as, to screen coal.

**Screening-machine** (skren'ing-ma-shen), n. An apparatus, having a rotary motion, used for screening or sifting coal, stamped ores, and the like.

**Screenings** (skren'ingz), n. pl. The refuse matter left after sifting coal, &c.

**Scroigh-of-day** (skresh'ov-dä), n. [Comp. D. krieken van den dag, peep of day; krieken, to peep, to chirp.] The first dawn. (Scotch.)

**Screw** (skru), n. [Same word as Dan skru, Sw. skruv, Icel. skruva, D. schroef, O.D. schroove, L.G. schruue, G. schraube, a screw. Or perhaps from O Fr. escroue, the hole in which a screw turns, Mod Fr. écrou, which Littré regards as from one or other of the above words, but Dies, rather improbably, derives from L. scroba, scrobia, a trench. The word does not appear very early in English. Shakespeare uses the verb, and no doubt the noun was familiar before this.] 1. A cylinder of wood or metal having a spiral ridge (the thread) winding round it in a uniform manner, so that the successive turns are all exactly the same distance from each other, and a corresponding spiral groove is produced. The screw forms one of the six mechanical powers, and is simply a modification of the inclined plane, as may be shown by cutting a piece of paper in the form of a right-angled triangle, so as to represent an inclined plane, and applying it to a cylinder with the perpendicular side of the triangle, or altitude of the plane, parallel to the axis of the cylinder. If the triangle be then rolled about the cylinder, the hypotenuse which represents the length of the plane will trace upon the surface of the cylinder a spiral line, which, if we suppose it to have thickness, and to protrude from the surface of the cylinder, will form the thread of the screw. The energy of the power applied to the screw thus formed is transmitted by means of a hollow cylinder of equal diameter with the solid or convex one, and having a spiral channel cut on its inner surface so as to correspond exactly to the thread raised upon the solid cylinder. Hence the one will work within the other, and by turning the convex cylinder, while

sand, lime, gravel, &c. It consists of a rectangular wooden frame with wires traversing it longitudinally at regular intervals. It is propped up in nearly a vertical position, and the materials to be sifted or screened are thrown against it, when the finer particles pass through and the coarser remain. A similar apparatus is used for separating lump coal from the small coal and dross, and also for sorting crushed ores, &c. — 4. In arch. the other remains fixed, the former will pass through the latter, and will advance every revolution through a space equal to the distance between two contiguous turns of the thread. The convex screw is called the *external* or *male*, and the concave or hollow screw the *internal* or *female* screw, or they are frequently termed simply the screw and nut respectively. As the screw is a modification of the inclined plane it is not difficult to estimate the mechanical advantage obtained by it. If we suppose the power to be applied to the circumference of the screw, and to act in a direction at right angles to the radius of the cylinder, and parallel to the base of the inclined plane by which the screw is supposed to be formed, then the power will be to the resistance as the distance between two contiguous threads to the circumference of the cylinder. But as in practice the screw is combined with the lever, and the power applied to the extremity of the lever, the law becomes. The power is to the resistance as the distance between two contiguous threads to the circumference described by the power. Hence the mechanical effect of the screw is increased by lessening the distance between the threads, or making them finer, or by lengthening the lever to which the power is applied. The law, however, is greatly modified by the friction, which is very great. The uses of the screw are various. It is an invaluable mechanism for fine adjustments such as are required in good telescopes, microscopes, micrometers, &c. It is used for the application of great pressure, as in the screw-jack and screw-press; as a bore, in the gimlet; and in the ordinary screw nail we have it employed for fastening separate pieces of material together. — *Archimedean screw*. See ARCHIMEDEAN. — *Endless screw* or *perpetual screw*. In this case the power does not depend upon the interval between the threads of either screw, but on the difference between the intervals in the two screws. See HURDIS SCREW and DIFFERENTIAL SCREW under DIFFERENTIAL. — *Screw propeller*, an apparatus which, being fitted to ships and driven by steam, propels them through the water, and which, in all its various forms, is a modification of the common screw. remains the epitome of shaft, but now it consists of several distinct blades. The usual position for the screw propeller is immediately before the stern-post, the shaft passing parallel to the keel, into the engine-room, where it is set in rapid motion by the steam engines. This rotary motion in the surrounding fluid, which may be considered to be in a partially inert condition produces, according to the well known principle of the screw an onward motion of the vessel more or less rapid, according to the velocity of the shaft, the obliquity of the arms, and the weight of the vessel. The annexed figure shows one of the recent forms of the screw propeller. — *Screw masts* and *wood screws*, a kind of screws very much used by carpenters and other mechanics for fastening two or more pieces of any material together. It generally shows itself by hard indolent tumours of the glands in various parts of the body, but particularly in the neck, behind the ears and under the chin, which after a time suppurate and degenerate into ulcers, from which, instead of pus, a white curdled matter is discharged. Scrofula is not contagious, but it is often a hereditary disease; its first appearance is most usually between the third and seventh year of the child's age, but it may arise between this and the age of puberty; after which it seldom makes its first attack. It is promoted by everything that debilitates, but it may remain dormant through life and not show itself till the next generation. In mild cases the glands, after having suppurated, slowly heal; in others, the eyes and eyelids become inflamed, the joints become affected, the disease gradually extending to the ligaments and bones, and producing a hectic and debilitated state under which the patient sinks; or it ends in tuberculated lungs and pulmonary consumption. A non-metallic element extracted from the pyrite of Fahln in Sweden, and discovered in 1818 by Berzelius. In its general chemical analogies it is related to sulphur and tellurium. It generally occurs in very small quantity in some of the varieties of iron pyrites and as an impurity in native sulphur. When precipitated it appears as a red powder, which, when heated, melts, and on cooling forms a brittle mass, nearly black, but transmitting red light when in thin plates. When heated in the air it takes fire, burns with a blue flame, and produces a gaseous compound, oxide of selenium, which has a most penetrating and characteristic odour of putrid horse-radish.

**Self** (self). [A Sax. *seif*, *seifa*, a pronominal word common to the Teutonic tongues; O. Sax. *seif*, D. *seif*, Dan. *seif*, Icel. *seif*, G. *selb*, *selbst*, Goth. *siiba*; probably formed by compounding the reflexive pronoun *se*, *si* (=I *se*), seen in Icel. *sef*, to himself, *sik*, self, G. *sich*, with some other word. In the oldest English (A. Sax.) as well as later *seif* was a kind of pronominal adjective, most commonly used after the personal pronouns, but also, in the sense of same, standing before nouns, quite like an adjective. Thus the following forms occur: *ic seif*, or *ic selfa*, I myself; *min selfes*, of myself; *me selfum*, to myself; *me sefne* (acc.), myself; *thû selfa*, thyself; *hê selfa*, himself; *we seife*, we ourselves; on *thâm sylfan gedre*, in that same year, &c. The dative of the personal pronoun was also prefixed to *seif*, the latter being undeclined, as *ic me seif*, I myself; *hê him seif*, he himself; and these forms gradually led to the forms *myself*, *thyself*, *ourselves*, &c., in which the genitive or possessive form is prefixed to *seif*. After this it was not unnatural for *seif* to be often regarded as a noun with the plural *seifes*, like other nouns ending in *f*. In *himself*, *themselves*, the old dative is still retained.) A pronominal element affixed to certain personal pronouns and pronominal adjectives to express emphasis or distinction; also when the pronoun is used reflexively. Thus for emphasis, I *myself* will write; I will examine for *myself*. Thou *thyself* shalt go; thou shalt see for *thyself*. The child *itself* shall be carried; it shall be present *itself*. Reciprocally, I abhor *myself*; he loves *himself*; it pleases *itself*; we value *ourselves*. Except when added to pronouns used reflexively, *self* serves to give emphasis to the pronoun, or to render the distinction expressed by it more emphatical. 'I *myself* will decide,' not only expresses my determination to decide, but the determination that no other shall decide. *Himself*, *herself*, *themselves*, are used in the nominative case, as well as in the objective.

Jesus *himself* baptized not, but his disciples. Jn. iv. 2.

Sometimes *self* is separated from *my*, *thy*, &c., as, *my wretched self*; 'To our gross *seives* (Shak.); and this leads to the similar use of *self* with the possessive case of a noun; as, 'Tarquin's *self*' (Shak.), giving *self* almost the character of a noun, which it fully takes in such cases as are illustrated in next article.

It is reported by Josephus to have been made in the reign and by the order of Ptolemy Philadelphus, king of Egypt, about 270 or 280 years before the birth of Christ. It is supposed, however, by modern critics that this version of the several books is the work, not only of different hands, but of separate times. It is probable that at first only the Pentateuch was translated, and the remaining books gradually. The Septuagint was in use up to the time of our Saviour, and is that out of which most of the citations in the New Testament from the Old are taken. It is an invaluable help to the right understanding of the Hebrew Scriptures.

Speculatively applied at the universities to one not likely to pass his examination. [Colloq.]

Other circumstances occurred . . . which seemed to show that our director was what is not to be found in Johnson's dictionary—rather *shaky*. *Thackeray*

**Shale** (shál), *n.* [A form of *scale* or *shell*; G. *schale*, a skin or bark, a shell, a thin layer. See **SHILL**.] 1. A shell or husk.

Your fair show shall suck away their souls Leaving them but the *shales* and husks of men. *Shak.*

2. In *geol.* a species of schist or schistuous clay; slate clay; generally of a bluish or yellowish gray colour, more rarely of a dark blackish or reddish gray, or grayish black, or greenish colour. Its fracture is slaty, and in water it moulders into powder. It is often found in strata in coal-mines, and commonly bears vegetable impressions. It is generally the forerunner of coal. Bituminous shale is a sub-variety of argillaceous shale, is impregnated with bitumen, and burns with flame. It yields, when distilled at a low red heat, an oil of great commercial importance, to which, from its being rich in paraffin, the name of paraffin-oil has been given. The coal-measures of Linlithgowshire are especially rich in bituminous shales of great value. Alum also is largely manufactured from the shales of Lancashire, Yorkshire, and Lanarkshire. There are sandy, calcareous, purely argillaceous, and carbonaceous shales.

**Shale** (shál), *v. t.* To peel.

Like an ice upper grades was bursting its shell, or was *shaling* off its husk. *Ts. Taylor.*

**Shall** (shál), originally *v. t.*, now only auxiliary. Pres. I *shall*, thou *shalt*, he *shall*, pl. 1, 2, and 3 *shall*; imper. *should*, *shouldst* or *shouldst*, *should*, pl. *should*. [Formerly *shoul*, *shoul*, *shoul*, pret. *shoulde*, *shoulde*; A. Sax. *shool*, *shool*, I shall, I have to, I ought; pl. *sculan*, pret. *scoldde*, *scoldde*, inf. *sculan*. This is a preterite present, that is a preterite which has been transformed into a present, having thus acquired a new preterite of its own.

Similar forms occur throughout the Teutonic tongues, all regarded as from a verb signifying to kill; so that *shall* originally meant I have killed; hence, I have become liable for the werld, then I owe, I ought, I shall.] 1.† As independent verb: (a) to owe; to be under obligation for. 'By that faith I *shalt* to God.' *Chaucer.* (b) Have to; be called upon; be obliged; must. [In this sense almost the auxiliary.]

First tel me whider I *shall* go) and to what man *Chaucer.*

All dreary was his chere and his looking  
When that he *shold* out of the chambre go. *Chaucer.*

2. As an auxiliary: (a) to express mere futurity, forming the first persons singular and plural of the future tense (including the future perfect), and simply foretelling or declaring what is to take place—am to, are to; as, I or we *shall* ride to town on Monday. This declaration simply informs another of a fact that is to take place. Of course there may be an intention or determination in the mind of the speaker, but *shall* does not express this in the first person, though *will* does, I *will* go, being equivalent to I am determined to go, I have made up my mind to go. Hence, I *will* be obliged, or we *will* be forced, to go is quite wrong. The rest of the simple future is formed by the auxiliary *will*; that is to say, the future in full is, I *shall*, thou *wilt*, he *will*, we *shall*, you *will*, they *will*. In indirect narrative, however, *shall* may express mere futurity in the second and third persons in such sentences as, he says or thinks he *shall* go. (b) In the second and third persons *shall* implies (1) control or authority on the part of the speaker, and is used to express a promise, command, or determination; as, you *shall* receive your wages; he *shall* receive his wages; these phrases having the force of a promise in the person uttering them; thou *shalt* not kill; he may refuse to go, but for all that he *shall* go. (2) Or it implies necessity or inevitability, futurity thought certain and answered for by the speaker.

Sorrow on love hereafter *shall* attend. *Shak.*  
He that escapes me without some broken limb  
*shall* acquit him well. *Shak.*

(c) Interrogatively, *shall* I go? *shall* we go? *shall* he go? *shall* they go? ask for direction or refer the matter to the determination of the person asked. But *shall* you go? asks rather for information merely as to the future without referring to another's intention. (d) After conditionals, as *if* or *whether*, and in dependent clauses generally, *shall*, in all the persons, expresses simple futurity; as,

(I *shall* say, or we *shall* say,  
If Thou *shalt* say, ye or you *shall* say,  
He *shall* say, they *shall* say.

Whosoever (=if any one) therefore *shall* break one of these least commandments, and *shall* teach men so, he *shall* be called the least, &c. Mat. v. 19.

(e) *Should*, though in form the past of *shall*, is not used to express simple past futurity; thus, I *shall* go, means I am to go, but we do not say I *should* go yesterday, for I was to go or to have gone yesterday. In the indirect speech, however, it is so used; as, I said I *should* go; I arranged that he *should* go.

The Parliament resolved that all pictures . . . *should* be burned. *Macaulay.*

*Should* is very commonly used (1) to express present duty or obligation, as I, we, they *should* (now and always) practise virtue; or to express past duty or obligation; as, I *should* have paid the bill on demand; it was my duty, your duty, his duty to pay the bill on demand, but it was not paid.

(2) To express a merely hypothetical case or a contingent future event, standing in the same relation to *would* that *shall* does to *will*; thus, as we say I *shall* be glad if you will come, so we say I *should* be glad if you would come. In such phrases as, if it *should* rain to-morrow, if you *should* go to London next week, if he *should* arrive within a month, it is to be regarded as the future subjunctive. In like manner *should* is used after *though*, *grant*, *admit*, *allow*, &c. (3) It is often used in a modest way to soften a statement; thus, 'I *should* not like to say how many there are,' is much the same as I hardly like, I do not like; so I *should* not care if I were at home' = I do not. Similarly, 'It *should* seem' often is nearly the same as

'It seems'—but this expression is now less common than 'it would seem.'

He is no sutor then? So it *should* seem.

*B. Jonson.*  
*Shall* and *will* are often confounded by inaccurate speakers or writers, and even writers such as Addison sometimes make a slip. In quoting the following lines from a song in Sir George Etherege's 'She Would if she Could' (1704), Mr. B. Grant White says, 'I do not know in English literature another passage in which the distinction between *shall* and *will* and *would* and *should* is as once so elegantly, so variously, so precisely, and so compactly illustrated.'

How long I *shall* love him I can no more tell,  
Than, had I a fever, when I *should* be well.  
My passion *shall* kill me before I *will* show it;  
And yet I *would* give all the world he did know it;  
But oh how I *sigh*, when I think *should* he woo me,  
I cannot refuse what I know *would* undo me.

As by *rooffast* our fathers understood that which was firm and fast by its root, so by *shamefast*, in like manner, that which was established and made fast by (an honourable) *shame*. 1. In England, the chief officer of the crown in every county or shire, who does all the sovereign's business in the county, the crown by letters-patent committing the custody of the county to him alone. Sheriffs are appointed by the crown upon presentation of the judges in a manner partly regulated by law and partly by custom (see *PRICKING*); the citizens of London, however, have the right of electing the sheriffs for the city of London and the county of Middlesex. Those appointed are bound under a penalty to serve the office, except in specified cases of exemption or disability. As keeper of the queen's peace the sheriff is the first man in the county, and superior in rank to any nobleman therein during his office, which he holds for a year. He is specially intrusted with the execution of the laws and the preservation of the peace, and for this purpose he has at his disposal the whole civil force of the county—in old legal phraseology, the *posse comitatus*. The most ordinary of his functions, which he universally executes by a deputy called *under-sheriff*, consists in the execution of writs. The sheriff only performs in person such duties as are either purely honorary—for instance, attendance upon the judges on circuit—or as are of some dignity and public importance, such as the presiding over elections and the holding of county meetings, which he may call at any time.—2. In Scotland, the chief local judge of a county. There are two grades of sheriffs, the chief or superior sheriffs and the sheriffs-substitute (besides the lord-lieutenant of the county, who has the honorary title of sheriff-principal), both being appointed by the crown. The chief sheriff, usually called simply the sheriff, may have more than one substitute under him, and the discharge of the greater part of the duties of the office now practically rests with the sheriffs-substitute, the sheriff being (except in one or two cases) a practising advocate in Edinburgh, while the sheriff-substitute is prohibited from taking other employment, and must reside within his county. The civil jurisdiction of the sheriff extends to all personal actions on contract, bond, or obligation without limit, actions

The word passed into the Romance tongues from the Teutonic, our *skiff* being re-borrowed from the *Fr. esquif*; so also *esquip*. Probably connected with *shape*. *Icel. skapa*, to shape, *skipa*, to arrange, order. Some derive it from root signifying to dig or hollow out, whence *L. scapha*, *Gr. skaphē*, a bowl, a boat, a skiff; *Gr. skapto*, to dig.] 1. A vessel of some size adapted to navigation; a general term for vessels of whatever kind, excepting boats. Ships are of various sizes and fitted for various uses, and receive various names, according to their rig and the purposes to which they are applied, as man-of-war ships, transports, merchantmen, barques, brigs, schooners, luggers, sloops, yachts, galleys, &c. The name, as descriptive of a particular rig, and as roughly implying a certain size, has been used to designate a vessel furnished with a bowsprit and three masts—a main-mast, a fore-mast, and a mizen-mast—each of which is composed of a lower-mast, a top-mast, and a top-gallant mast, and carries a certain number of square sails. The square sails on the mizen distinguish a ship from a barque, a barque having only fore-and-aft sails on the mizen. But the development of steam navigation, in which the largest vessels have sometimes only a schooner rig and sometimes four masts, has gone far towards rendering this restricted application of the term ship of little value. Owing to increase of size, and especially increase in length, some sailing vessels now have four masts, and this rig is said to have certain advantages. Up to within recent times wood, such as oak, pine, &c., was the material of which all ships were constructed, but at the present day it is being rapidly superseded by iron and steel; and in Britain, which is the chief ship-building country in the world, the tonnage of the wooden vessels constructed is but a fraction of that of those built of iron. The first iron vessel classed as Lloyd's was built at Liverpool in 1838, but iron barges and small vessels had been constructed long before this.—*Armed ship*. See under ARMED.—*Ship's papers*, the papers or documents required for the manifestation of the property of the ship and cargo. They are of two sorts, viz. An instrument for separating the smaller particles of substances from the grosser, as flour from bran. Sieves are made of various forms and sizes to suit the articles to be sifted; but in its most usual form a sieve consists of a hoop from 2 to 8 inches in depth, forming a flat cylinder and having its bottom, which is stretched tightly over the hoop, constituted of basket-work, coarse or fine hair, gut, skin perforated with small holes, canvas, muslin, lawn, net-work, or wire, according to the use intended. In agriculture sieves are used for separating corn or other seed from dust or other extraneous matter. — *Drum sieve*, a kind of sieve in extensive use amongst druggists, dyers, and confectioners, so named from its form. It is used for sifting very fine powders, and consists of three parts or sections, the top and bottom sections being covered with parchment or leather, and made to fit over and under a sieve of the usual form, which is placed between them. The substance to be sifted being thus closed in, the operator is not annoyed by the clouds of powder which would otherwise be produced by the agitation, and the material under operation is at the same time saved from waste. — 2. Silica (s'il-ka), *n.* [*L. silice silice, a flint.*] (*sil-ka*) Oxide of silicon. This important substance constitutes the characteristic ingredient of a great variety of minerals, among which rock-crystal, quartz, chalcedony, and flint may be considered as nearly pure silica. It also predominates in many of the rocky masses which constitute the crust of our globe, such as granite, the varieties of sandstone, and quartz rock. It is the chief substance of which glass is made, also an ingredient, in a pulverized state, in the manufacture of stoneware, and it is essential in the preparation of tenacious mortar. Silica, when pure, is a fine powder, hard, insipid, and

moderately rough to the touch, and scratches and wears away glass. It combines in definite proportions with many salifiable bases, and its various compounds are termed silicates. Plate-glass and window-glass, or, as it is commonly called, crown-glass, are silicates of sodium or potassium, and flint-glass is a similar compound, with a large addition of silicate of lead. See *SILICATE*.

Silicate (s'il-i-kāt), *n.* A salt of silicic acid. Silicates formed by the union of silicic acid, or silica, with the bases alumina, lime, magnesia, potassa, soda, &c., constitute the greater number by far of the hard minerals which encrust the globe. The silicates of potash and soda, when heated to redness, form glass. -Silicate paint, natural silica, when dried and forming an almost impalpable powder, mixed with colours and oil. Unlike the ordinary lead paints, all the silicate colours are non-poisonous. Silicate white has great covering power, is not affected by gases, and heat of 500° is successfully resisted.

Silicic acid has not been obtained in the pure form, as it undergoes decomposition into water and silica when heated. Many silicic acids are believed to exist. The normal acid is  $H_2SiO_3$ .

Among the algae the name is given to a similar vessel, pod-like, oblong, conical, linear, or lanceolate, transversely striated, and formed either of transformed branches or portions of a branch. It is not quite certain that these are connected with the reproduction of the plant. See *SILICUA*.

Silico-fluoric (s'il-i-kō-flō-ō-ō-ik), *a.* The name of an acid,  $H_2SiF_6$ . When silicic acid is dissolved by hydrofluoric acid a gas is produced which is colourless, fuming strongly in the air. It is absorbed by water and hydrated silicic acid is deposited, while an acid is found in the water which is termed silico-fluoric acid, or hydrofluosilicic acid. With bases this acid forms salts called silico-fluorides, which are nearly all insoluble.

The fine, soft thread produced by the larvæ of numerous species belonging to the genus *Bombyx* and other genera of the family *Bombycidae*, lepidopterous insects of the section popularly known by the name moth, the most important of which is the *Bombyx mori*, or common silkworm, a native of the northern provinces of China. **Silk** is the strongest, most lustrous, and most valuable of textile fabrics, and is a thread composed of several finer threads which the worm draws from two large organs or glands, containing a viscid substance, which extend along great part of the body, and terminate in two spinnerets at the mouth. With this substance the silkworm envelops itself, forming what is called a cocoon. *Raw silk* is produced by the operation of winding off, at the same time, several of the balls or cocoons (which are immersed in hot water to soften the natural gum on the filament) on a common reel, thereby forming one smooth even thread. Before it is fit for weaving it is converted into one of three forms, viz. *singles*, *tram*, or *organzine*. *Singles* (a collective noun) is formed of one of the reeled threads, being twisted in order to give it strength and firmness. *Tram* is formed of two or more threads twisted together. In this state it is commonly used in weaving, as the *shoot* or *weft*. *Thrown silk* is formed of one, two, three, or more singles, according to the substance required, twisted together in a contrary direction to that in which the singles of which it is composed are twisted. The silk so twisted is called *organzine*. *Spun silk* is waste silk, pierced cocoon, floss, &c., dressed, combed, formed into rovings, and spun by processes and on machinery analogous to that used in the worsted manufacture. — *Tussah silk*, a term applied to the raw silk produced by a variety of moths other than the ordinary silkworm, *Bombyx mori*. — 2. Ag.* At wt 109. 1. A metal which in its compact state is of a fine white colour and lively brilliancy. It possesses

the metallic lustre in a remarkable degree, is capable of being highly polished, and has neither taste nor smell. Its sp. gr. is about 10.5. A cubic foot weighs about 660 lbs. Its ductility is little inferior to that of gold. It is harder and more elastic than tin or gold, but less so than copper, platinum, or iron. It is superior to gold in lustre, but inferior to it in malleability; it is, however, so malleable that it may be beaten into leaves not exceeding the 100,000th part of an inch in thickness. It is not altered by air or moisture, but is blackened or tarnished by sulphuretted hydrogen. The numerous uses and applications of silver are well known. In its pure state it is too soft for coin, plate, and most ornamental purposes, and is therefore in such cases alloyed with copper, by which, in proper proportion, its colour is not materially impaired, and it is considerably hardened. The standard silver of our coin is an alloy 222 parts of pure silver, and 18 of copper. Native silver occurs abundantly, and is generally alloyed with gold, platinum, copper, iron, arsenic, cobalt, &c., most frequently with platinum. The ores of silver are numerous, and indeed there are few metallic ores which do not contain some traces of it. The principal ores are the following: *Monochloride of silver*, or *horn-silver*, a soft bluish-gray mineral found chiefly in Chili and Peru, but also in smaller quantities in Siberia, the Hartz, Norway, Saxony, Brittany, and Cornwall; it contains about 75 per cent of silver. *Argentite, vitreous sulphide of silver*, or *silver-glance*, a dark leaden-gray ore, with a metallic lustre when cut, found in Saxony, Bohemia, Hungary, and Mexico; it contains about 86 per cent of silver. *Brittle or black sulphide of silver* or *stephanite*, a brittle, blackish mineral found at Freiberg, in Peru, and Mexico; it contains about 67 per cent of silver. *Polybasite*, another form of the brittle sulphide, is of an iron-gray colour, and found in Mexico, Chili, Nevada, and Idaho; it contains from 64 to 72 per cent of silver. *Dark-red silver ore, ruby-silver*, or *Pyrargyrite*, a widely disseminated ore, yields about 60 per cent of silver. *Native amalgam*, a soft mineral of a bright silver-white appearance, is found in many localities, and contains about 36 per cent of silver. *Argentiferous galena*, the sulphide of lead, which yields a variable amount of silver, is reckoned very rich when it contains 0.005. — *Fulminating silver*, a very explosive powder formed by heating aqueous nitrate of silver with strong nitric acid and alcohol. See FULMINATING. — *German silver, nickel silver*. See GERMAN-SILVER, NICKEL-SILVER. — 2. Money; coin made of silver. — 3. A piece of plate, or utensil for domestic use, made of silver. —*Simile, Metaphor, Allegory, Parable*, agree in implying likeness between a primary object, or the thing likened, and a secondary, or that to which it is likened. *Simile* asserts mere resemblance, and states what is literally true: as, man is *like* grass. *Metaphor* asserts what, taken literally, is not true, affirming the primary to be the secondary; as, all flesh is grass. *Allegory* has been defined to be a continued metaphor, but improperly. *Metaphor* presents always both objects; *allegory*, the secondary only, so that its real meaning and application are only to be perceived by inference. The most characteristic feature of *allegory* is the personification of abstract ideas and things without life, and the allegory generally forms an independent whole of some length. *Spenser's Faery Queen* and Bunyan's *Pilgrim's Progress* are the most perfect examples in modern literature. *Parable* is usually devoted to the inculcation of some truth or principle by means of an invented case or incident resembling or parallel to a real case, the author of the parable being thus enabled to put prominently and forcibly forward the essential points intended to be emphasized.

Its intense, dry, parching heat, combined with the cloud of dust and sand which it carries with it, has a very destructive effect upon both vegetable and animal life. The effects of the simoom are felt in neighbouring regions, where winds owing their origin to it are known under different names, and it is subject to important modifications by the nature of the earth's surface over which it passes. **Siphoid** (sif'-oid), *a.* (Fr *siphon*) A vessel or apparatus of French construction for receiving and giving out aerated water.

**Siphon, Syphon** (sif'-on), *n.* (Or *siphon*, a hollow tube, a reed.) 1. A bent pipe or tube whose legs are of unequal length, used for drawing liquid out of a vessel by causing it to rise in the tube over the rim or top. For this purpose the shorter leg is inserted in the liquid, and the air is exhausted by being drawn through the longer leg. (See fig. 1.) The liquid then rises by the weight of the atmosphere till it reaches the top of the vessel, and then descends in the lower leg of the siphon, and continues to flow till the liquid in the vessel reaches the level of the end of the shorter leg. The action of the siphon depends on the difference between the lengths of the two legs, estimated in a perpendicular direction, the shorter leg being always inserted in the liquid. Sometimes an exhausting tube is placed on the longer leg for exhausting the air by suction (see fig. 2), and causing the flow to commence, but the more general method is to fill the tube in the first place with the liquid, and then stopping the mouth of the longer leg to insert the shorter leg in the vessel; upon removing the stop the liquid will immediately begin to flow. The limits within which the siphon can act are determined by the specific gravity of the fluid. Water cannot be raised by the siphon to a

greater height than 33 feet, nor mercury to a greater height than 30 inches. — *Waterbury siphon* (so called from its having been first used in that place), a siphon with both legs equal, and turned up at the extremities, in which case so long as the extremities are kept on the same level, it will continue always full and ready for use. — 2. In *anat.* (a) one of the membranous and calcareous tubes which traverse the septa and the interior of polythalamous shells. (b) The tubular prolongation of the mantle in certain univalves and bivalve molluscs, used for conveying water to or from the gills. In this sense also called *Siphonite*.

**Siphon** (sif'-on), *v.t.* To convey, as water, by means of a siphon, to transmit or remove by a siphon.

There are several varieties of siphon-barometers, but the most convenient is that invented by Gay Lussac. The tube is hermetically sealed at both ends, after having been filled with mercury, and the communication with the atmosphere takes place through a small capillary hole drilled laterally through the short turned-up branch near its upper extremity. This orifice is so small that while it allows the air to pass freely, it prevents the escape of the mercury. This barometer is very convenient for carriage, and is easily brought to a position proper for observation.

**Siphon-bottle** (sif'-on-bot'-l), *n.* A bottle containing aerated water which may be discharged through a bent tube by the pressure of the gas.

**Siphon-cup** (sif-on-kup), *n.* In weak form of lubricating apparatus in which the oil is led over the edge of the vessel by capillary action, ascending and descending in a certain wick, and dropping on the journal.

Some of the Codices resemble corallines from the amount of carbonate of lime which enters into their composition.

**Siphon-gauge** (sif-on-gaj), *n.* An instrument consisting of a glass siphon, partially filled with mercury, for indicating the degree of rarefaction which has been produced in the receiver of an air pump. A gauge of this kind is also used to ascertain the degree of vacuum in the condenser of a steam-engine, and to indicate the pressure of a fluid contained in a vessel, when greater than the pressure of the external atmosphere, and also the pressure of liquids, as water in pipes, &c.

**Siphonia** (sif-on-ee), *n.* [Gr *siphon*, a hollow tube, a pipe, from the use made of the crinoid.] A genus of plants belonging to the nat. order Euphorbiaceae, consisting of about half-a-dozen species. **Sir** (sir), [Fr. *sire*, from L. *senior*, an older or elderly person (see SENIOR), through the forms *sen*, *senior*, *sindus*, *sider*, *sire* *Breaket*.] A common complimentary title of address now used without consideration of rank or status, a general title by which a speaker addresses the person he is speaking to used in the singular and plural. 'Speak on, sir.' *Shak.* 'But, sire, be sudden in the execution.' *Shak.* While generally used as a title of respect, as by servants to their masters, sons to their fathers, scholars to their teachers, and the like, it is frequently employed in phrases expressing great displeasure, astonishment, doubt, &c., or conveying a threat, reproach, or the like. Thus in *The Rivals*, by Sheridan, Sir Ant. Absolute addresses his son, 'What's that to you, sir?' 'Odds life, sir' if you have the estate you must take it with the live stock on it,' and so on. - 2. A title of honour of knights and baronets, in this case always prefixed to the Christian name. 'Noble captain, your servant—Sir Arthur, your slave.' *Barry.*

2. A title formerly given to clergymen, as the Bishopric of Sir Hugh Evans, a Welsh parson. 'Sir Oliver Marten, a vicar.'

A title formerly applied to priests and curates in general, for the reason, however, the academical title of a bachelor of arts, was usually rendered by *sir* in English at the universities. So that a bachelor, who in the books stood *Domine* Brown, was in conversation called *Sir Brown*. Therefore, as most clerical persons had taken that first degree, it became usual to style them *Sir*.

So usual indeed did the practice alluded to

by Nares become that a 'Sir John' came to be a common sobriquet for a priest.

Instead of a faithful and pious teacher, they knew a Sir John, which both better still in playing at tables than in God's word.

4. Used also as a common noun to signify (a) lord, master. 'Sole sir of the world.' *Shak.* (b) Gentleman. 'A nobler sir ne'er lived.' *Shak.*

**Siren** (sire), *n.* [Gr. *sirein*, a siren, supposed to mean fit an entangler, from *sirein*, a cord.] 1. In Greek myth one of several (according to some writers, three) nymphs, who by their singing fascinated those that sailed by their island, and then destroyed them. In works of art they are

supplied both with lungs and external gills. They are peculiar to the southern provinces of the United States. Called also *Mud-eels*. 6. An instrument for producing continuous or musical sounds, and for measuring the number of sound waves or vibrations per second, which produce a note of given pitch. In its original form it consists of a disc with a circular row of oblique holes, revolving close to the top-plate of a wind-chest perforated with corresponding holes of a contrary obliquity, so that the jets of air from the latter passing through the former keep the disc in motion, and produce a note corresponding to the rapidity of the coincidences of the holes in the two plates, the number of coincidences or vibrations to a given time being shown by indices which connect by toothed wheels with a screw on the axis of the disc. From the deep piercing nature of the sound which the siren emits, a modified form of the instrument having two discs rotating with great velocity in opposite directions is employed as a fog-signal or alarm. The discs are driven by a steam-engine, which also forces a blast of steam through their apertures when those of the two discs come in opposition. The device is placed at the smaller extremity of a large trumpet, which greatly intensifies the sound. Called also *Sirene*.

**Siren** (sî'ren), *a.* Pertaining to a siren or to the dangerous enticements of music; bewitching; fascinating; as, a *siren song*.

This order comprises the manatee and dugong. They differ from the Cetacea in having the nostrils placed at the anterior part of the head, and in having molar teeth with flat crowns adapted for a vegetable diet. They feed chiefly on seaweeds, and frequent the mouths of rivers and estuaries. Besides these living members the Sirenia were represented by a gigantic species 25 feet long and 20 in circumference. It was a native of Behring's Straits, but is now extinct, no specimen having been seen for 200 years. The Sirenia have existed since the miocene period.

**Sirenian** (sî-rê-ni-an), *a. and n.* Of or belonging to the order Sirenia; as a noun, one of the Sirenia.

When full grown they form a silken cocoon, in which they undergo transformation.

**Smell** (*smel*), *n.* 1. The sense or faculty by which certain qualities of bodies are perceived through the instrumentality of the olfactory nerves; the faculty of perceiving by the nose; one of the five senses. The essential part of the organ of smell consists of the expansion of the olfactory nerves, the first or most anterior pair of the nerves issuing from the brain, whose minutest branches are distributed just beneath the mucous membrane of the nose. The air, passing through the nose, brings the effluvia or odoriferous particles of bodies into contact with the olfactory nerves, the nerves transmit the impression to the brain, by means of which it is perceived by the mind. The human organ of smell is less developed than that of some other mammals, or even of birds. In different animals the sense of smell is adapted chiefly to that class of substances on which they feed. In the choice of food, which is the main object of the sense of smell, man generally, though almost unconsciously, and animals always, exercise the precaution of smelling, and they instinctively form a judgment according to the impression received. In eating also, much of that which is commonly attributed to the sense of taste depends upon the odour of the food carried from the mouth to the nose.—2. The quality of any thing or substance, or emanation therefrom, which affects the olfactory organs; odour; scent; perfume; as, the smell of mint; the smell of geranium. 'The rankest compound of villainous smell that ever offended nostril.' *Shak.*

This operation requires to be conducted differently according to the different metallic ores. In regard to iron, the ore, after having been roasted or calcined in a kiln, in order to drive off the water, sulphur, and arsenic with which it is more or less combined in its native state, is subjected to the heat of a blast-furnace, along with certain proportions of coke and limestone, which latter serves as a flux. (See BLAST-FURNACE.) Copper is reduced at once from its oxides in shaft-furnaces (furnaces resembling blast-furnaces); but the sulphurets must first be roasted, then smelted for matte by reducing in shaft or reverberatory furnaces, again roasted, and again smelted, and so on until a matte is produced rich and pure enough to give raw copper after another roasting and final reducing smelting. Lead is smelted directly from very pure galena in one operation by a blast on the blast-hearth. It is also sometimes roasted in a reverberatory furnace and reduced in a shaft furnace.

The exhalation, visible vapour, or substance that escapes or is expelled in combustion from the substance burning; applied especially to the volatile particles expelled from vegetable matter, or wood, coal, peat, &c.; the matter expelled from metallic substances being more generally called *fume* or *fumes*. In its more extended sense the word smoke is applied to all the volatile products of combustion, which consist of gaseous exhalations charged with minute portions of carbonaceous matter or soot; but, as often used in reference to what are called smoke-consuming furnaces, the term is frequently employed to express merely the carbonaceous matter which is held in suspension by the gases. Various methods have been devised for the removal of smoke or for the cure of smoky chimneys, and also for the consumption and purification of smoke. The methods employed for the latter purpose all merge into one common principle; namely, that of mixing air with the combustible vapours and gases generated by the action of heat on pitcoal, so that they may be made to burn with flame, and become entirely converted into incombustible and transparent invisible vapours and gases.

**S**lake which falls is composed of a number of minute crystals of ice, which present countless modifications of the hexagonal system. They have great diversities of density, and display innumerable varieties of the most beautiful forms. These crystals adhere together to form an irregular cluster; and consequently the incident rays of light, which are refracted and reflected so as to present individually the prismatic colours, are scattered after reflection in all directions, and combine to give to the eye the colour sensation of white. When sufficient pressure is applied the slightly adhering crystals are brought into true molecular contact, when the snow, losing its white colour, assumes the form of ice. Snow answers many valuable purposes in the economy of nature. Accumulated upon high regions it serves to feed, by its gradual melting, streams of running water, which a sudden increase of water, in the form of rain, would convert into destructive torrents or standing pools; and in many countries it tempers the burning heats of summer by cooling the breezes which pass over it. In severer climates it serves as a defence against the rigours of winter by protecting vegetation from the frost, and by affording a shelter to animals which bury themselves under it. Even in more temperate climates it is found that vegetation suffers more from an open winter than when the fields, during that season, lie hid beneath a snowy covering; for as snow is a slow conductor of heat a coating of it prevents the earth from parting quickly with its warmth, and at the same time protects it from the cold of the atmosphere.—*Red snow.* See *PROTOCOCCUS*. 2. Something that resembles snow, as white blossoms. 'The scent of the elder bushes which were spreading their summer snow close to the open window opposite.' *George Eliot.*—*Snow* is often used in the formation of compounds, many of which are self-explanatory, as *snow-capped*, *snow-crowned*, *snow-mantled*, and the like.

**SNOW** (snô), *n.* [*D. sneeuw*, a kind of boat, from *L.G. snau*, a snout, a beak.] A vessel equipped with two masts, resembling the main and fore masts of a ship, and a third small mast just abaft and close to the main-mast, carrying a try-sail. It is identical with a *brig*, except that the brig bends her fore and aft main-sail to the main-mast, while the *snow* bends it to the try-sail mast.

**SNOW** (snô), *v. i.* To fall in snow: used chiefly impersonally, as, it *snows*; it *moved* yesterday.

**SNOW** (snô), *v. t.* To scatter or cause to fall like snow. 'Till age *snows* white hairs on thee.' *Donne.*

Let it thunder to the tune of Green Sleeves, hail kissing-comfits and *snow* eringoes. *Shak.*

**Snow-apple** (snô'ap-l), *n.* A species of apple.

This limit is called the snow-line, or line of perpetual congelation, and the mountains which rise above it are always covered with snow. The snow-line varies according to latitude, being highest near the equator and lowest near

The snow-plough for ordinary country roads usually consists of boards framed together so as to form an acute angle in front, and spread out behind to any required distance. The angular point or edge is made to enter the snow, and the machine being propelled by horses harnessed to the centre framework, the snow is thrown off by the boards to the sides of the road, and thus a free passage is opened up for wheel-carriages, &c. For railway purposes snow-ploughs are of various forms, adapted to the character of the country, the amount of snowfall, the tendency to drift, &c.

E. snub*, a snag, a short stump of wood. In meaning 2 it may be directly from *Icel. snubba*, to snub, to chide, the older *E. form* being *snab*, *snypbe*. G. *seifa*, from same root as *L. sebum*, tallow; *L. sapo*, soap, appears to have been borrowed from the old German.] 1. A chemical compound of common domestic use for washing and cleansing, and also used in medicine, &c. It is a compound resulting from the combination of certain constituents derived from fats, oils, grease of various kinds both animal and vegetable, with certain salifiable bases, which in household soaps are potash and

soda. Chemically speaking soap may be defined as a salt, more especially one of the alkaline salts of those acids which are present in the common fats and oils, and soluble soaps may be regarded as oleates, stearates, and margarates of sodium and potassium. There are many different kinds of soaps, but those commonly employed may be divided into three classes:—1. Fine white soaps, scented soaps, &c.; 2. Coarse household soaps; 3. Soft soaps. White soaps are generally combinations of olive-oil and carbonate of soda. Perfumes are occasionally added, or various colouring matters stirred in while the soap is semifluid. Common household soaps are made chiefly of soda and tallow. Yellow soap is composed of tallow, resin, and soda, to which some palm-oil is occasionally added. Mottled soap is made by simply adding mineral and other colours during the manufacture of ordinary hard soap. Marine soap, which has the property of dissolving as well in salt-water as in fresh, is made of cocoa-nut oil, soda, and water. Soft soaps are generally made with potash instead of soda, and whale, seal, or olive oil, or the oils of linseed, hempseed, rape-seed, &c., with the addition of a little tallow. Excellent soaps are made from palm-oil and soda. Soap is soluble in pure water and in alcohol; the latter solution jellies when concentrated, and is known in medicine under the name of *opodeldoc*, and when evaporated to dryness it forms what is called transparent soap. Medicinal soap, when pure, is prepared from caustic soda, and either olive or almond oil. It is chiefly employed to form pills of a gently aperient acid action.—2. Flattery. [Slang.] **Soap** (sôp), *v. t.* [From the noun.] 1. To rub or wash over with soap.—2. To flatter. [Slang.]

**Soda** (*sod'a*), *n.* [*Sp. Pg. and It. soda, glass-*

...wort, barilla, from *Ar. suad, soda*.] ( $\text{Na}_2\text{O}$ )

The protoxide of the metal sodium, formerly

called mineral alkali. It has likewise been

called a fixed alkali, in contradistinction

from ammonia, which is a volatile alkali.

*Soda*, or protoxide of sodium, is formed when

sodium is burned in dry air or oxygen. It

is a white powder, which attracts moisture

and carbonic acid from the air. When this

protoxide is dissolved in water, there is  
formed the true alkali or hydrate of sodium,  
called also caustic alkali,  $\text{NaHO}$ , which is a  
white brittle mass of a fibrous texture, hav-  
ing a specific gravity of 1.586. Caustic soda  
has a most corrosive taste and action upon  
animal substances: it dissolves readily both  
in water and alcohol, in the solid form it  
readily attracts carbonic acid from the at-  
mosphere, falling thereby into an efflorescent  
carbonate. It forms soaps with tallow, oils,  
wax, rosin; dissolves wool, hair, silk, horn,  
alumina, silica, sulphur, and some metallic  
sulphides. With acids soda forms salts  
which are soluble in water, and many of  
which crystallize. The carbonate of soda,  
 $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ , is the soda of commerce in  
various states, either crystallized, in lumps,  
or in a crude powder called soda-ash. The  
manufacture of carbonate of soda is divided  
into three branches. The first process is  
the decomposition of sea-salt or common  
salt (chloride of sodium) by means of sul-  
phuric acid; the second, the conversion of  
the sulphide of sodium so produced into  
crude carbonate of soda by strongly heating  
with chalk and carbonaceous matter; and  
third, the purification of this crude carbo-  
nate, either into a dry white soda-ash or into  
crystals. The chief uses of soda are in the  
manufacture of glass and of hard soap. The  
carbonate of soda is used in washing, and  
is a powerful detergent, although milder  
than carbonate of potash. It is also used  
in medicine. Sulphate of soda is glauber-  
salt. See **SODIUM**.

**Soda-alum** (*sod'a-al-um*), *n.* A crystalline  
mineral, a hydrated double sulphate of  
aluminum and sodium, found on the island  
of Milo, at Solfatara, and near Mendoza, on

ture of caustic soda and quicklime, used  
chiefly for nitrogen determinations in or-  
ganic analysis.

a stone.] A mineral; so called from the  
large portion of soda which enters into its  
composition. It is of a bluish-green colour,  
and found crystallized or in masses. Besides  
soda it contains silica, alumina, and hydro-  
chloric acid.

**Soda-paper** (*sod'a-pé-pér*), *n.* A paper satu-

having soda for its base.

**Soda-water** (*sod'a-wá-ter*), *n.* A refreshing  
drink generally consisting of ordinary water  
into which carbonic acid has been forced  
under pressure. On exposure to the ordinary  
atmospheric pressure the excess of carbonic  
acid escapes, thus causing effervescence.  
It rarely contains soda in any form. It is  
useful in cases of debility of the stomach,  
accompanied with acidity.

**Sod-burning** (*sod'ber-níng*), *n.* In agri.  
the burning of the turf of old pasture-lands  
for the sake of the ashes, as manure.

**Soder** (sô'dér), *n.* Solder.

**Sodium** (sô'di-um), *n.* [See SODA.] Sym. Na (from *Natrium*). At. wt. 23. The metal of which soda is the oxide, discovered by Davy in 1807. He obtained it by a process exactly similar to that by which he procured potassium, which it strongly resembles in many properties. Gay-Lussac and Thénard soon afterwards procured it in greater quantity by decomposing soda by means of iron; and Brunner showed that it may be prepared with much greater facility by distilling a mixture of sodic carbonate with charcoal: it is now prepared by the latter process in considerable quantities. Sodium is a silver-white metal, having a very high lustre. Its sp. gr. is 0.972; it melts at 194° Fahr., and oxidizes rapidly in the air, though not so rapidly as potassium. It decomposes water instantly, but does not spontaneously take fire when thrown on water, unless the water be somewhat warm, or the progress of the globule of sodium upon the surface of the water be impeded. When heated in air or oxygen it takes fire and burns with a very pure and intense yellow flame. It is perhaps more abundant in our globe than any other metal, for it constitutes two-fifths of all the sea-salt existing in sea-water, in the water of springs, rivers, and lakes, in almost all soils, and in the form of rock-salt. Sea-salt is a compound of chlorine with sodium. Sodium also occurs as oxide of sodium or soda in a good many minerals; and more especially in the form of carbonate, nitrate, and borate of soda. Soda is contained in sea plants, and in land plants growing near the sea. It occurs also in most animal fluids. The only important oxide of sodium is the protoxide known as soda. See SODA.

See *SPECTRUM*.—*Solar spots*, dark spots that appear on the sun's disc, usually visible only by the telescope, but sometimes so large as to be seen by the naked eye. They indicate the sun's revolutions on its axis, are very changeable in their figure and dimensions, and vary in size from mere points to spaces of 50,000 miles or more in diameter. The frequency of solar spots attains a maximum every ten-and-a-half years, falling off during the interval to a minimum, from which it recovers gradually to the next maximum. This periodicity has been thought to be intimately connected with meteorological phenomena.—*Solar system*, in *astron.* that system of which the sun is the centre. To this system belong the planets, planetoids, satellites, comets, and meteorites, which all directly or indirectly revolve round the central sun, the whole being bound together by the mutual attractions of the several parts. According to the *Ptolemaic system*, framed by the

Greek astronomer Ptolemy, the earth was an absolutely fixed centre, and the heavens were considered as revolving about it from east to west, and carrying along with them all the heavenly bodies, the stars and planets, in the space of twenty-four hours. The *Copernican system*, taught by Copernicus in the beginning of the sixteenth century, represents the sun to be at rest in the centre of the universe, and the earth and the several planets as revolving about him as a centre, while the moon and the other satellites revolve about their primaries. The heavens and fixed stars were supposed to be at rest, and their apparent diurnal motions were imputed to the earth's motion from west to east. Notwithstanding the defects of this system it produced a powerful effect, and prepared the way for the discoveries of Galileo, Kepler, and Newton. The *Tychonic system*, propounded by Tycho Brahe, the Danish astronomer, in the latter part of the sixteenth century, represented that the earth was fixed in the centre of the universe, and that round it revolved the sun and moon, while the planets revolved directly round the sun. Brahe's observations were of immense service to his contemporary Kepler in discovering the famous laws which ultimately led Newton to the grand theory of universal gravitation. (See *KEPLER'S LAWS*.) The *Newtonian system*, so named as being adopted by Sir Isaac Newton, is the only one admitted in modern astronomy. It is frequently called the *Copernican system*, from its rejecting what Copernicus rejected; but it is far from receiving all that Copernicus received. In this system there is no fixed centre, the sun only approximating to that character from its greater magnitude. The orbits of the planets, which all revolve round the sun, are ellipses, of which the elements vary.—*Solar telegraph*, a telegraph in which the rays of the sun are projected from and upon mirrors. The duration of the rays makes the alphabet, after the manner of the dot-and-dash telegraphic alphabet; a heliostat (which see).—*Solar time*. The same as *Apparent Time*. See *TIME*.—*Solar year*. **Soldier** (sol'dér), *n.* One who or a machine which solders.

**Soldering** (sol'dér-ing), *n.* The process of uniting the surfaces of metals, by the intervention of a more fusible metal, which being melted upon each surface, serves, partly by chemical attraction, and partly by cohesive force, to bind them together. The alloy used as a solder must not only be more fusible than the metal or metals to be united, but must also have a strong affinity for them. The solder usually contains a large proportion of the metal to which it is to be applied, in combination with some more easily fusible metal. The surfaces to be united must be made perfectly clean and free from oxide. This is commonly effected by scraping the surfaces; and in order that the formation of any oxide may be prevented during the process, borax, sal ammoniac, or rosin is used, either mixed with the solder or applied to the surfaces. — *Autogenous soldering* is the union of two pieces of metal without the intervention of any solder, by fusing them at the point of junction by jets of flame from a gas blowpipe or by other means.

**Somnambulism** (sôm-nam'bû-lizm), *n.* [See SOMNAMBULATE.] A peculiar perversion of the mental functions during sleep, in which the subject acts automatically. The organs of sense remain torpid and the intellectual powers are blunted. During this condition some instinctive excitation may take place, and there may be the production of impulses, in consequence, of different kinds. Walking in sleep is the most palpable, but

not the most marvellous characteristic of this condition. The person affected may perform many voluntary actions implying to all appearance a certain degree of perception of the presence of external objects. The somnambulist gets out of bed, often dresses himself, goes out of doors, and walks frequently over very dangerous places in safety. On awaking in the morning he is either utterly unconscious of having stirred during the night, or remembers it as a mere dream. Sometimes the transactions of the somnambulist are carried much farther; he will mount his horse and ride, or go to his usual occupation. In some cases somnambulists are capable of holding conversation. Somnambulism occurs in the sensitive and excitable, often in conjunction with other nervous affections, and is hereditary. As denoting a musical composition, *song* is used to signify a vocal melody of any length or character, and not confined to a single movement; but as regards performance, it is generally confined to an air for a single voice—airs for more than one voice being, however, sometimes called part-songs. The octave of the proper sonnet consists of two quatrains, the rhymes of which are restricted to two—one for the first, fourth, fifth, and eighth lines; the other for the second, third, sixth, and seventh. In the *sestette*, which is commonly made up of two tercets, the rhymes may be two or three, variously distributed. The sonnet generally consists of one principal idea, pursued through the various antitheses of the different strophes. The lightness and richness of the Italian and Spanish languages enable their poets to express every feeling or fancy in the sonnet; but with us it has been found most suitable to grave, dignified, and contemplative subjects.—2. **Sound** (sound), *n.* [O.E. *soun*, *souns*, from Fr. *son*, L. *sonus*, a sound; cog. Skr. *soan*, to sound. The *d* has been added, as in *round* (to whisper), *lend*, *kind* (a labourer).] 1. That which is heard; the effect which is produced by the vibrations of a body affecting the ear; an impression, or the effect of an impression, made on the organs of hearing by the vibrations of the air or other medium with which these organs are in contact, which vibrations are caused by the vibrations or tremulous motions of the sounding body; noise; report; as, the *sound* of a trumpet or drum; the *sound* of the human voice; a horrid *sound*; a charming *sound*; a sharp *sound*; a high *sound*; a loud *sound*; a low *sound*; an acute *sound*; a grave *sound*. No body can emit a sound unless it be put into a tremulous or vibratory motion; and hence sound, considered with respect to the sounding body, consists of a motion of vibration impressed on the parts of the body; this motion is communicated to the air which surrounds the body, and produces in it corresponding undulations, by which the ear being affected the sensation of sound is produced. The propagation of sound is not instantaneous, that is to say, the sensation is not produced at the same instant as the motion in the sonorous body which causes it; for if a gun or a piece of ordnance be discharged at a considerable

distance the flash will be first seen, and after some seconds have elapsed the report will be heard. In like manner lightning always precedes thunder, and if the thunder cloud be at a considerable distance several seconds will elapse before the thunder is heard. It has been ascertained that the velocity of sound through air at 0° Centigrade is about 1090 feet per second. The velocity is modified by such causes as the wind, and is affected by the temperature, pressure, and humidity of the air at the time. Sound is propagated or radiates from the sounding body in all directions and in straight lines, and diminishes in intensity as it recedes from the sounding body; so that at different distances from the body it is inversely as the squares of those distances. When sound is arrested in its progress by a smooth, hard, or elastic surface, as a rock, the wall of a house, of a cavern, or of a vault, it is thrown back or reflected, and thus forms what is called an *echo*, the law of the reflection being that the angle of reflection is always equal to the angle of incidence. Sounds are usually classified under the two heads of *noises* and *musical sounds*. A musical sound is caused by a regular series of exactly similar disturbances or pulses succeeding each other at precisely equal intervals of time. If these conditions are not fulfilled the sound is a noise. Musical sounds differ in *intensity*, in *pitch*, and in *quality*; *intensity* depends upon the amplitude of the vibrations; *pitch* depends upon the number of vibrations in a stated time (sound is audible, as a general rule, when the number of vibrations are more than 16 and less than 36,000 per second); the *quality* of a sound depends on the configuration or internal structure of the individual sound-waves. See *ACOUSTICS*.—2. Noise without significance; empty noise; noise and nothing else.

But leaving out as irrelevant all considerations of the mode in which we come by our ideas of *space*, and of bodies as occupying *space*, it will I think be admitted that the antithesis between bodies and an ability to contain bodies truly represents the contrast in our conceptions of the sensible non-ego (matter) and the insensible non-ego (*space*). *H. (b) The science of pleading, which, until the passing of an act in 1852, constituted a distinct branch of the law, having the merit of developing the points in controversy with great precision. Its strictness and subtlety were frequently a subject of complaint, and one of the objects of the act was to relax and simplify its rules. (c) A popular term for the specious but unsound or unfair argumentation of one whose aim was victory rather than truth.—*Special property*, a qualified or limited property, as the property which a man acquires in wild animals by reclaiming them.—*Special tail* is where a gift is restrained to certain heirs of the donee's body, and does not descend to the heirs in general.—*Special verdict* is a verdict in which the jury find the facts and state them as proved, but leave the law arising from the facts to be determined by the court.

**Specie** (spé'shi), *n.* [The ablative form of *L. species*, and so used as an English word probably from its occurrence in the frequent phrase 'paid in *specie*.' See **SPECIES**.] Gold, silver, &c., coined, and used as a circulating medium of commerce; hard money; coin: in contradistinction to paper-money, as bank-notes, bills, &c.

**Species** (spé'shéz), *n. sing. and pl.* [*L.*, a seeing, that which is seen, appearance, shape, a peculiar sort, kind, or quality, from *L. specio*, to look at, to behold: *Gr. skeptō, skeptomai*; *Skr. pash*, to see; akin *spile, spire, spy, despise, respect, spectacle*, &c. Meaning 6 is derived from the fact that in *L. Latin species* (both in sing. and pl.) came from having the meaning of wares in general to have the meaning of valuables, precious goods. In French it is the plural *espèces* that is used for *specie*.] 1. Visible or sensible representation; appearance to the senses or the mind; sensible or intellectual representation; an image. [Rare.]

An apparent diversity between the *species* visible and audible is that the visible doth not mingle in the medium, but the audible doth. *Bacon.*

2. † A public spectacle or exhibition; a show. Shows and *species* serve best with the people. *Bacon.*

3. A class, collection, or assemblage of things or beings classified or associated according to attributes or properties which are determined by scientific observation; as, (a) a group of animals or plants which generally bear a close resemblance to each other in the more essential features of their organization, which produce fertile progeny, and which may, in the generality of cases, produce individuals varying from the general type of the group, the variation, however, being in all cases of a limited kind. Under this definition the various species, 'kinds' of animals and plants, and their included varieties may be comprehended; and this mode of stating the idea of species at the same time leaves the great question of the 'origin of species,' raised chiefly by Darwin and his followers, an open one, and one which must be left for future observers to settle. Up till a recent time naturalists regarded species as unchanging throughout the longest succession of ages, except within narrow and marked limits. Thus Buffon defines a species as 'a constant succession of individuals similar to, and capable of reproducing each other,' and Cuvier as 'a succession of individuals which reproduces and perpetuates itself.' (b) In mineralogy, chemistry, and such sciences as relate to inorganic substances, species is regarded by some writers as being determined by identity of physical properties, as specific gravity, hardness, &c.; and by others, as constituted by chemical composition, the natural properties going for nothing. In scientific classification species unite to form groups called genera, which are included in orders, the orders forming classes, and so on.—4. In logic, a group of individuals agreeing in common attributes and designated by a common name; a conception subordinated to another conception, called a genus or generic conception, from which it differs in containing or comprehending more attributes, and extending to fewer individuals; thus 'man' is a *species* under 'animal' as a genus, and 'man' in its turn may be regarded as a genus with respect to European, Asiatic, and the like.—5. Kind; sort; variety; description; as, a coarse *species* of wit; a *species* of low cunning; a fine *species* of cloth; a rare *species* of generosity.—6. † Metal coined into a circulating medium; coin; specie.

**Specimen** (spék'í-men), *n.* [L. *specimen*, lit. that by which a thing is seen and recognized, a mark or token, an example or specimen, from *specio*, to look, to behold. See **SPECTES**.] A part or small portion of anything intended to exhibit the kind of the whole, or of something not exhibited; a sample; as, a *specimen* of painting or composition; a *specimen* of one's art or skill. — *Specimen, Sample.* A *specimen* is a portion of a larger whole employed to exhibit the nature or kind of that of which it forms a part, without reference to the relative quality of individual portions; thus a cabinet of mineralogical *specimens* exhibits the nature of the rocks from which they are broken. A *sample* is a portion taken out of a quantity, and implies that the quality of the whole is to be judged by it, and not rarely that it is to be used as a standard for testing the goodness, genuineness, purity of the whole, and the like. In many cases, however, the words are used indifferently.

In open market-place produced they me,  
To be a public *spectacle* to all. Shak.

2. Anything seen; a sight. 'The dreadful *spectacle* of that sad house of pride.' Spenser. — 3. *pl.* A well-known and invaluable optical instrument used to assist or correct some defect in the organs of vision. Spectacles consist of two oval or circular lenses mounted in a light metal frame which is made up of the 'bows,' bridge, and 'sides' or 'temples.' The frame is so constructed as to adhere to the nose and temples, and keep the lenses in the proper position. Spectacles which are merely fixed on the nose are usually called eye-glasses. Spectacles with convex lenses are used to aid the sight of the aged, or those who are termed long or far sighted; and spectacles with concave lenses are used to assist the vision of those who are near-sighted. In long-sighted persons the refractive powers of the eye are too feeble, or the cornea is too much flattened; hence, the rays of light coming from an object after entering the eye do not converge sufficiently soon to be brought to a focus, and form a perfect image of the object on the retina. The convex lens counteracts this defect by increasing the convergence of the rays, and causing them to meet at the retina. Short-sightedness is a defect the very reverse of that which has been stated, and hence must be corrected by opposite means, namely, by concave lenses. In both cases the value of spectacles depends upon their being accurately adapted to the state of the eye. Spectacles with coloured lenses, as green, blue, neutral-tint, smoke-colour, &c., are used to protect the eyes from a glare of light. *Divided spectacles* have each lens composed of two semicircles of different foil neatly united; one half for looking at distant objects, and the other for examining things near the eye.

Another kind, called *periscope spectacles*, has been contrived in order to allow considerable latitude of motion to the eyes without fatigue. The lenses employed in this case are either of a meniscus or concavo-convex form, the concave side being turned to the eye. Spectacles with glazed wings or frames partly filled with crape or wire-gauze are used to shield the eyes from dust, &c. Spectacles, as they form an instrument of binocular power, are usually designated a *pair of spectacles*. — 4. † The eye; the organ of vision.

And bid mine eyes be packing with my heart  
And called them blind and dusky *spectacles*,  
For losing ken of Albion's wished coast. Shak.

2. An image of something seen, continuing after the eyes are closed, covered, or turned away. If, for example, we look intently with one eye upon any coloured object, such as a wafer placed on a sheet of white paper, and immediately afterwards turn the same eye to another part of the paper, we shall see a similar spot, but of a different colour. Thus, if the wafer be red, the seeming spot will be green; if black, it will be changed into white. These images are also termed *ocular spectra*.

3. The oblong figure or stripe formed on a wall or screen by a beam of light, as of the sun, received through a small hole or slit and refracted by being passed through a prism. This stripe is coloured throughout its length, the colours shading insensibly into one another from red at the one end, through orange, yellow, green, blue, indigo, to violet at the other. This analysis is due to the different refrangibilities of the component rays, the violet being the most refrangible and red the least. Besides the coloured rays, the spectrum contains thermal or heating rays, and chemical rays. The heating effect of the solar spectrum increases in going from the violet to the red, and still continues to increase for a certain distance beyond the visible spectrum at the red end, while the chemical action is very faint in the red, strong in the blue and violet, and sensible to a considerable distance beyond the violet end. The actinic rays, or those beyond the violet, may be rendered visible by throwing them upon a surface treated with some fluorescent substance. (See **ACTINISM**.) A pure spectrum of solar light is crossed at right angles by numerous dark lines, called *Fraunhofer's lines* (which see), each dark line marking the absorption of a particular elementary ray. By means of these dark lines and certain bright lines analogous to them, to be referred to, facts of the highest importance, especially in chemistry, have been ascertained. For the proper understanding of the import of these lines, five principles require to be kept in view. *First*, an incandescent solid or liquid body gives out a *continuous* spectrum. *Second*, an incandescent gaseous body gives out a *discontinuous* spectrum, consisting of bright lines. *Third*, each element when in the state of an incandescent gas gives out lines peculiar to itself. *Fourth*, if the light of an incandescent solid or liquid passes through a gaseous body, certain of its rays are absorbed, and black lines in the spectrum indicate the nature of the substance which absorbed the ray. *Fifth*, each element, when gaseous and incandescent, emits bright rays identical in colour and position on the spectrum with those which it absorbs from light transmitted through it. Now, applying these principles to the solar spectrum, we find, from the nature and position of the rays absorbed, that its light passes through hydrogen, potassium, sodium, calcium, barium, magnesium, zinc, iron, chromium, cobalt, nickel, copper, and manganese, all in a state of gas, and constituting part of the solar envelope, whence we conclude that these bodies are present in the substance of the sun itself, from which they have been volatilized by heat. The moon and planets have spectra like that of the sun, because they shine by its reflected light, while, on the other hand, each fixed star has a spectrum peculiar to itself. It has been already said that the incandescent vapour of each elementary substance has a characteristic spectrum, consisting of fixed lines, which never changes. This furnishes the chemist with a test of an exquisitely delicate nature for the detection of the presence of very minute quantities of elementary bodies. Thus, by heating any substance till it becomes gaseous and incandescent and then taking its spectrum, he is able by the lines to read off, as it were, from the spectrum the various elements present in the vapour. Four new elements, viz. rubidium, cesium, indium, and thallium, have thus been detected. The employment of the spectrum for the detection of the presence of elementary bodies, whether by observing the

rays they absorb or those they emit, is called *spectrum* or *spectral analysis*, and the instrument employed a *spectroscope* (which see).

The head and chest are united to form a segment known as a cephalothorax, no wings are developed, and breathing is effected by means of pulmonary or lung sacs. Spiders are remarkable for spinning webs for taking their prey and forming a convenient habitation. The abdomen of the spiders is unjointed, and is furnished with from four to six cylindrical or conical mammillae or processes, with fleshy extremities, which are perforated with numerous small orifices for the passage of silky filaments of extreme tenacity, with which they form their webs, and which proceed from internal reservoirs. The legs number four pairs, and no antennae are developed. Their mandibles are terminated by a movable hook, fixed inferiorly, underneath which, and near its extremity, which is always pointed, is a little opening that allows a passage to a venomous fluid contained in a gland of the preceding joint. After wounding their prey with their hooked mandibles, they inject this poison into the wound, which suddenly destroys the victim. A very great diversity exists in the modes in which spiders construct their webs, and in the situations in which they are placed. Some spiders do not catch their prey by entangling them in their webs, but roam abroad in search of them.

Weaves tedious mazes to trap mine enemies. Shaks.

This original substance in which all antagonism between mind and matter, liberty and necessity, &c., ceases, all objects of finite consciousness disappear he called God, by which he understood that which has an independent existence, and the understanding of which does not require the idea of anything else.

This substance is infinite, and might also exist. It is incapable of creating anything material or intellectual, for all matter and mind are comprehended in itself. Its attributes are infinite thought and infinite extension. God, this all embracing being, can act only in accordance with the established order, for otherwise we must suppose him capable of a change of nature, or that there exists a nature different from his own.

Thought and extension spirit and matter finite and infinite motion and repose good and evil, causes and effects are attributes of this sole substance, which produces nothing but modifications of itself. All that exists is only a necessary succession of modes of being in a substance for ever the same.

The fibres coil either from right to left, or the reverse, somewhat in the manner of a corkscrew. The fibres may be single or double, or it may be composed of numerous threads. Their function is supposed to be that of the conveyance of air. They are very seldom found in the root or bark of wood, but are frequently abundant in the other parts, especially in the leaves and flowers. They are easily discovered on breaking asunder the leaves and stalks of many plants when the fibres may be unravelled, and present themselves as delicate filaments like the threads of a cobweb. The woodrat shows (1) a compound spiral vessel, (2) three simple spiral vessels. — **Spiral vessels**, in man, a species of ganglion which serves the same purpose as horse veins, and is better adapted for light machinery. The teeth are formed upon the circumference of cylinders of the required diameter at an angle with their respective axes, when the direction of the motion is to be changed. By this construction the teeth become in fact small portions of screws or spirals winding round the cylinders, whence the name. Wheels of this kind are used when the two shafts require to pass each other, when the shafts are in the same plane, bevel wheels are employed.

'With glistering spira and pinnacles adorns'd.' Milton.

Utter your jubilee, steeple and spire! Tennyson.

The earliest spira, in the architectural sense, were merely pyramidal or conical roofs, specimens of which still exist in Norman buildings. These roofs, becoming gradually oblongated and more and more acute, resulted at length in the elegant tapering spire, among the many existing examples of which, probably that of Salisbury is the finest. The spira of medieval architecture (to which alone spira are appropriate) are generally square, octagonal, or circular in plan, they are sometimes solid, more frequently hollow, and are variously ornamented with bands encircling them, with pinnacles more or less enriched, and with spire lights, which are of infinite variety. Their angles are sometimes crocketed, and they are almost invariably terminated by a finial. In the later styles the general pyramidal outline is obtained by diminishing the diameter of the building in successive stages, and this has been imitated in modern spira, in which the forms and details of classic architecture have been applied to structures essentially medieval. The term spira is sometimes restricted to signify such tapering buildings, crowning towers or turrets, as have pinnacles at their base. When the spire rises from the exterior of the wall of the tower without the intervention of a parapet it is called a *bracket* (which see). — 4 A stalk or blade of grass or other plant.

**Spongiida**, **Spongiida** (spun/'jā-dā, spun/'jā-dā), *n. pl.* An order of Protozoa or lowest animals, class Rhizopoda, sometimes elevated into a distinct class. The members are composed of two elements, an internal supporting framework or skeleton, and a soft gelatinous investing substance called *corium*, or 'bark.' The framework consists of the horny, reticulated, elastic fibres of a substance called *areolae*, which interlace in every direction, strengthened by calcareous, or, more generally, by siliceous spicules. This framework is the sponge of commerce. On examining it we find it filled with pores, having larger openings or canals at wider distances, called *oscula* or *venti*. The sponge-bark investing this framework is composed of an aggregation of organisms, protoplasmic, and amoebiform bodies, some dilated and others capable of emitting pseudopodia. A constant circulation of water goes on in the living sponge, the currents being drawn in by the pores and expelled by the oscula by means of vibratile cilia lodged in cells or chambers situated beneath the superficial layer, and by this circulation the animal is nourished. Reproduction takes place both by gemmation and true ova. In the skeletons of the true calcareous and all other sponges the keratins are wanting. Sponges have been classified into three groups: (a) Myxospongiae, in which no skeleton of any kind exists. Springs are used for various purposes—diminishing concussion, as in carriages; for motive power, acting through the tendency of a metallic coil to unwind itself, as in clocks and watches; or to communicate motion by sudden release from a state of tension, as the bow to the arrow, the spring of a gun-lock, &c.; others are employed to measure weight and other force,

as in the spring-balance, as regulators to control the movement of wheel-works, &c. 5. Any active power; that by which action or motion is produced or propagated.

6. A natural fountain of water; an issue of water from the earth, or the basin of water at the place of its issue. Springs have their origin in the water which falls upon the earth, and sinks through porous soils till it arrives at a stratum impervious to water, where it forms subterranean reservoirs at various depths. When confined in this manner it is subject to the pressure of the water which fills the channels through which it has descended, and when this pressure is sufficient to overcome the resistance of the superincumbent mass of earth the water breaks through the superficial strata, and gushes forth in a spring. In descending downwards and rising upwards through various mineral masses the water of springs becomes impregnated with gaseous, saline, earthy, or metallic admixtures, as carbonic acid gas, sulphuretted hydrogen gas, nitrogen, carbonate of lime, silica, carbonate of iron, &c. When these substances are present in considerable quantity the springs become what are known as *mineral springs*, acquiring the peculiar properties which give them their medicinal value. Warm and hot springs are common, especially in volcanic countries, where they are sometimes distinguished by violent ebullitions. (See **GEYSER**.) As a general rule springs are permanent in proportion to the depth to which the water which supplies them has descended from the surface. Some springs run for a time and then stop altogether, and after a time run again, and again stop; these are called *intermittent springs*. (See under **INTERMITTENT**.) Others do not cease to flow, but only discharge a much smaller quantity of water for a certain time, and then give out a greater quantity; these are called *variable* or *reciprocating springs*.

Same root as *stand*.] That branch of dynamics which treats of the properties and relations of forces in equilibrium—equilibrium meaning that the forces are in perfect balance, so that the body upon which they act is in a state of rest. According to the classification still employed by many writers on the subject the word *statics* is used in opposition to *dynamics*, the former being the science of equilibrium or rest, and the latter of motion, both together constituting *mechanics*. But among more recent authors *mechanics* is used to express not the theory of force and motion, but rather its application to the arts. The word *dynamics* is employed as expressing the science which treats of the laws of force or power, thus corresponding closely to the old use of the term *mechanics*; and this science is divided into *statics* and *kinetics*, the first being the science which treats of forces considered as producing rest, and the second as treating of forces considered as producing motion. The two great propositions in statics are that of the lever and that of the composition of forces; but it also comprehends all the doctrines of the excitement and propagation of forces or pressures through the parts of solid bodies by which the energies of machines are produced.—*Social statics*, that branch of sociology which treats of the forces which constitute or regulate society as it exists for the time being.

**Steam** (stém), *n.* [A. Sax. *stém*, *stedm*, steam, vapour, smoke; D. *stoom*, Fris. *stoame*, steam; L. G. *stüm*, drift of snow or rain. Perhaps from a root *stam*, signifying dark, seen without the *s* in Skr. *tamas*, darkness, *timira*, dark.] 1. The vaporous substance into which water is converted under certain circumstances of heat and pressure; water in a gaseous state. Water gives off vapour or steam at every temperature—a low temperature not preventing the formation of steam, but only decreasing its density. The term, however, is strictly applied to the elastic aeriform fluid generated by heating water to the boiling-point. When water in an open vessel is heated to the temperature of 212° F., or to the boiling-point, globules of steam are formed at the bottom, and rise to the surface; and the continued application of heat, even though increased indefinitely, will only cause a more copious and rapid formation of steam, and will finally evaporate the whole of the water without raising the temperature of either. In this case all the heat which enters into the water is solely employed in converting it into steam of the temperature of boiling water. But if the water be confined in a strong close vessel, both it and the steam which it produces may be brought to any

temperature; and as steam at 212° occupies nearly 1700 times the space of the water from which it is generated, it follows that, when thus confined, it must exercise an enormous elastic or expansive force, which may also be shown to be proportional to its temperature. Steam which has received additional heat apart from water is called *superheated steam*, and approximates to the condition of a perfect gas. Steam, however, as used in the steam-engine holds water in suspension mechanically, and differs sensibly from the condition of a perfect gas. It is called *saturated* or *wet steam*. When the temperature of saturated steam is considerably above 212° F the steam formed under such circumstances is termed *high-pressure steam*; at 212° F it is termed *low-pressure steam*, and its pressure is equal to that of one atmosphere, or 14.7 lbs. on the square inch. Steam in its perfect state is transparent, colourless, and invisible; but when it has been deprived of part of its heat by coming into contact with cold air, it suddenly assumes a cloudy appearance, and is condensed into water. Hence appears another important property of steam, its condensibility; so that whenever cold is applied to it it suddenly returns to the liquid state, and thus can be employed to produce a vacuum. From the properties above briefly adverted to, steam constitutes an invaluable agent for the production of mechanical force, as exemplified in the vast and multiplied uses of the steam-engine. Steam is also employed as an agent in distributing the heat used for warming buildings, in heating baths, evaporating solutions, distilling, brewing, drying, dyeing, and even for cookery. -2. In *popular usage*, the visible moist vapour which rises from water, and from all moist and liquid bodies, when subjected to the action of heat; as, the steam of boiling water, of malt, of a tan-bed, &c. improvements from the hands of Newcomen, Beighton, Blakey, and others. Still, however, it was imperfect and rude in its construction, and was chiefly applied to the draining of mines or the raising of water. Up to this time it was properly an atmospheric engine, as the actual moving power was the pressure of the atmosphere, the steam only producing a vacuum under the piston. The steam-engine was brought to a high state of perfection by the celebrated James Watt about the year 1782. The numerous and vital improvements introduced by him, both in the combination of its mechanism and in the economy of its management, have rendered the steam-engine at once the most powerful, the most easily applied and regulated, and generally speaking the least expensive of all prime movers for impelling machinery of every description.

**Steam-engine** (stém'en-jin), *n.* An engine worked by steam, or an engine in which the mechanical force arising from the elasticity and expansive action of steam, or from its property of rapid condensation, or from the combination of these principles, is made available as a source of motive power in the arts and manufactures, and in locomotion. The invention of the steam-engine has been ascribed by the English to the Marquis of Worcester, who published an account of it about the middle of the seventeenth century. By the French the invention has been ascribed to Papin towards the close of the same century. Papin's plan contained the earliest suggestion of a vacuum under a piston by the agency of steam. The first actual working steam-engine of which there is any record was invented and constructed by Captain Savery, an Englishman, to whom a patent was granted for it in 1698. This engine was employed to raise water by the expansion and condensation of steam. The steam-engine received great im-

Steam-engines vary much in magnitude, form, and proportions, as well as in the details of the machinery by which the power of the steam is applied, but all work upon substantially the same principles which were embodied in Watt's steam-engine, and to understand one is to understand all. The above illustration represents a sectional elevation of a *Condensing Steam-engine*. The construction and action of the steam-engine will be readily understood from this illustration. The pipe which conveys the steam from the boiler opens into the part marked l, which incloses a movable valve by means of which the steam may be alternately admitted into the cylinder a by the upper port c and lower d, between these points the piston b works steam-tight. The valve l is so contrived that while it allows steam to pass into the cylinder through one of the ports, it shall at the same time open a communication between the opposite side of the piston and the condenser n, which is a hollow vessel kept constantly immersed in cold water, a portion of which is admitted into it by the injection-cock o; consequently, the steam thus admitted is instantly deprived of its heat, and reconverted into its original form of water, thereby forming a vacuum. Thus it will be seen that, on the communication being opened up between the boiler and either side of the piston, the latter will ascend or descend in the cylinder unimpeded by the resistance of the atmosphere against the other side, and with a force proportional to the pressure of the steam, and as the motions of the steam-valve l are regulated by the engine itself, the above action is kept up continuously. The alternating rectilinear motion thus generated within the cylinder is trans-

rod, by means of a rod attached to the piston, to a strong beam *ff*, movable upon a central axis, a system of jointed rods *ee*, called the *parallel motion*, being interposed for the purpose of neutralizing the disturbing action which the circular path of the beam would otherwise exert upon the piston. The reciprocating motion of the beam is now, through the intervention of the connecting-rod *g* and crank *A*, converted into a circular or rotary motion, which is rendered continuous and uniform by the fly-wheel *h*, to the axis of which the machinery is to be impelled is connected. The air-pump *p* for withdrawing the vapour and water from the condenser, the feed pump *s* for supplying the boilers, and cold water pump *t* for supplying the condenser cylinders, are all worked by rods from the beam, and the governor *u* for maintaining uniformity of motion, is driven by a band from the crank-shaft. The above description refers more immediately to that class of steam-engines called *low-pressure* or *condensing engines*, in which the power derived from the rapid condensation of the steam is made available in combination with that due to its elasticity, but if we suppose the condensing apparatus removed, and the waste steam allowed to escape into the atmosphere, it will then be equally applicable to that kind called *high-pressure* or *non-condensing engines*, which employ the elastic action of the steam alone. Steam-engines are classified in various ways, as *portable*, *marine*, *locomotive*, *pumping*, *blowing*, *winding*, &c. According to the arrangement of the chief parts they are called as *beam*, *connecting-cylinder*, *horizontal*, *vertical*, &c. The mechanical energy of a steam-engine is usually estimated in horse-power. See HORSE-POWER.

**Steam-gauge** (*stém'gaj*), *n.* An attachment to a boiler to indicate the pressure of steam, a pressure-gauge. There are many forms. One of the older is a bent tube partially filled with mercury, one end of which springs from the boiler, so that the steam raises the mercury according to the amount of pressure. A very common form of gauge is that known as Bourdon's, which consists essentially of a flattened metal tube, closed at one end and bent circularly, into which the steam is admitted. As such a tube tends to straighten itself out by the force of the steam, the amount of pressure can easily be ascertained by an attached index apparatus.

**Steam-governor** (*stém'gu vörn-ér*). See GOVERNOR.

**Steam-gun** (*stém'gun*), *n.* A gun the propulsive force of which is derived from the expansion of steam issuing through a shotted tube.

**Steam-hammer** (*stém'ham-ér*), *n.* A form of heavy forge hammer operated by steam, consisting usually of a steam cylinder and piston, with metal strikers attached, placed vertically over the anvil. There are two principal varieties: in one the cylinder is fixed, and the hammer is attached to the piston-rod, and is operated by the direct action of the steam in the cylinder; in the other the piston is fixed, and the hammer is attached to the lower end of the cylinder, which usually rises and falls by the action of the steam in the cylinder. The former is known as *Nasmyth's*, and the latter as *Cochran's* hammer; which is shown in the cut attached. In the enlargement of the figure is a steam and exhaust valve, and attached to it a hollow piston-rod, acting as steam and exhaust pipe, to which the piston is attached on a fixture. The steam, being introduced into the cylinder or hammer immediately above the piston, presses the cylinder over,

and raises the hammer between the guides to the required height. The steam being then cut off, and the exhaust-valve opened,

Steam-hammer

the hammer falls, not only with the velocity of gravity, but with the additional velocity produced by the compression of the air under the piston during the latter portion of the hammer's ascent, which, acting as a recoil, adds considerably to the effect of the blow. With the most powerful hammer steam is also introduced on the under side of the piston, so as to augment still further the speed and force of the blow. The valves and valve-gearing are so arranged that the person in charge of the machine can arrest the motion of the hammer while falling, or cause it to fall at any moment while ascending. In Nasmyth's hammer two hammer cylinders move horizontally in the same line, but in opposite directions, and the piece to be forged is placed between the two. There are some other kinds of steam hammers suitable for light work, in most of which the hammer-head is attached to the end of a horizontal shaft which acts as a lever, the fulcrum of which is nearer the free end of the shaft than the end bearing the hammer. The hammer is raised by cams attached to a revolving drum, and falls when by the revolution of the drum the shaft is freed from one of the cams. These are often called *Steam-tide*.

great violence through the circular orifice, encounters the edge of the cup *c*, and thereby produces a loud and shrill sound which may be heard at the distance of several miles. Steam-whistles are made to give musical tones varying in pitch by graduating the length of the pipe or cup, and a series of whistles tuned to different notes and operated by keys forms the musical instrument called the calliope.

It exists in combination with glycerine as stearine, in beef and mutton fat, and in several vegetable fats, such as the butter of cacao. It is obtained from stearine by saponification and also from mutton suet by a similar process. Stearic acid is in the form of brilliant white scaly crystals. It is inodorous, tasteless, insoluble in water, but soluble in alcohol and ether. It burns like wax, and is used in the formation of candles. It forms compounds with the alkalies, earths, and metallic oxides, which are called stearates.

**Stearine**, *Stearin* (*stéat-éat*), *n.* (Or *stéar*, *stéat*.) ( $C_{18}H_{36}O_2$ ) 1. The chief ingredient of suet and tallow, or the harder ingredient of animal fats, oleine being the softer one. It is obtained from mutton suet by repeated solution in ether and crystallization. It may also be obtained by pressing tallow between hot plates, and afterwards dissolving in hot ether, which on cooling deposits the stearine. It has a pearly lustre, is soft to the touch, but not greasy. It is insoluble in water, but soluble in hot alcohol and ether. When treated with superheated steam it is separated into stearic acid and glycerine, and when boiled with alkalies is saponified, that is, the stearic acid combines with the alkali forming soap, and glycerine is separated. When melted it resembles

wax. There are three stearines, which may be all regarded as derivatives of glycerine in which one, two, or three OH groups are replaced by the radical stearyl. Natural stearine is the tristearyl derivative of glycerine.—2. A popular name for stearic acid as used in making candles.

It is found in metalliferous veins, with the ores of copper, lead, zinc, silver, and tin. It is a hydrated silicate of magnesia and alumina. Iron combined with a small portion of carbon. Steel usually contains also small quantities of silicon, phosphorus, manganese, and sulphur, but iron and carbon appear to be its only essential constituents. The relative proportions of iron and carbon vary in steel of different qualities; but in that used for ordinary purposes the carbon amounts from about 0.5 to 1.5 per cent, the toughness, tenacity, and hardness increasing with the increase of the carbon, the elasticity diminishing as the hardness increases, and *vice versa*. At a red heat steel is malleable and may be welded. The colour is a bright grayish white, the texture closely granular, the specific gravity varying from 7.62 to 7.81. Steel formed from bar-iron by cementation is called *blistered steel*, from its surface ac-

quiring a *blistered* character in the process. (See CEMENTATION.) When blistered steel is rolled or beaten down into bars, it is called *shear-steel*, and if it be melted, cast into ingots, and again rolled out into bars, it forms *cast-steel*. Cast-steel is now largely manufactured by what is known as Bessemer's process. (See BESSEMER'S PROCESS.)

*Natural or German steel* is an impure and variable kind of steel procured from cast-iron, or obtained at once from the ore. The natural steel yielded by cast-iron, manufactured in the refining houses, is known by the general name of *furnace steel*, and that which has only been once treated with a refining furnace is particularly called *rough steel*. The peculiarity of steel, upon which its high value in the arts in a great measure depends, is its property of becoming hard after being heated to redness and then suddenly cooled by being plunged into cold water, and of being again softened down to any requisite degree by the application of a certain temperature. This process is called *tempering*. It is found that the higher the temperature to which steel is raised, and the more sudden the cooling, the greater is the hardness; and hence, any degree of hardness can be given to steel which is required for the various purposes to which it is applied. According to the degree of hardness to which steel is tempered, it assumes various colours, and formerly these colours served as guides to the workman. Now, however, a thermometer, with a bath of mercury or oil, is employed, and the operation of tempering is performed with a much greater degree of certainty. 'The uses of steel in forming various kinds of instruments, edge-tools, springs, &c., are well known.—*Indian steel*. See WOOL.—2. *Fig.* a weapon; particularly, an offensive weapon, as a sword, spear, and the like.
